## Python 2025

Exercises 01 and 02

Deadline: 2025 17 April

*Virak  
Academy*

# **Exercise 01: Basics**

**Number of Questions: 5**

# Question01 (Basics)

For each of the following variables, try to cast them to the requested type. If the conversion is successful, write the resulting value. If not, explain why using a comment.

## Convert to int

```
price = "15.0"  
code = " 007 "  
name = "Alice"  
is_active = True
```

## Convert to float

```
score = "3.14"  
amount = "3,14"  
value = "NaN"  
is_logged_in = False
```

## Convert to str

```
age = 12  
average_score = 17.5  
is_verified = True
```

## Convert to boolean

```
username = ""  
status = "False"  
comment = " "  
visits = 0
```

# Question02(Basics)

**Explain the result of the following codes step by step and write comment for that line by line.**

```
price_str = "120.5"
price = int(float(price_str))
print("price =", price)

code = str(price) + "0"
print("code =", code)

result = code + price_str
print("result =", result)

final_price = float(result)
print("final_price =", final_price)

discounted = int(final_price)
print("discounted =", discounted)
```

# Question03(Basics)

**Write a Python program that takes two float numbers as input from the user. If both numbers are equal, print True. Otherwise, print False.**

# Question04(Basics)

**Write a Python program that swaps the values of two variables.**

```
price_str = "120.5"
price = int(float(price_str))
print("price =", price)

code = str(price) + "0"
print("code =", code)

result = code + price_str
print("result =", result)

final_price = float(result)
print("final_price =", final_price)

discounted = int(final_price)
print("discounted =", discounted)
```

# Question05(Basics)

**Write a Python program with the following variable assignments. Check the output for each one. If there's no error, comment on what the code does. If there's an error, fix it.**

```
price1, price2, price3 = 100, 200, 30.5  
score1 = score2 = 18.9  
str1, str2, str3 = 'python', 'java'
```

# **Exercise 02: String**

**Number of Questions: 4**

# Question01 (String)

**Write a Python program that:**

- Takes a string as input from the user.
- Displays the first, last, and middle character of the string. (If the string length is even, display either of the middle characters.)
- Displays the length of the string.
- Displays the characters from the string that are at even indexes (index 0, 2, 4, etc.).
- Displays the string in reverse.
- Displays the first half and the second half of the string.

# Question02(String)

**Write a Python program that takes a student ID from the user. If the ID is entirely a number, display True. Otherwise, display False**

# Question03(String)

**Write a Python program that takes a string as input from the user and removes all spaces from it, including the spaces at the beginning, end, and within the string.**

# Question04(String)

**Find two new methods for strings in Python that were not covered in class. Write an example to demonstrate their usage.**

# GOOD LUCK!

**Never give up!**

**we're with you every step of  
the way at **VirakAcademy****
